

LEVEL 1

Rect Transform is the size and positioning of the object, with “pos” being the position, meanwhile “width” and “height” are the proportions of the size, being for how long an object is and how tall an object is.

TextMeshPro – Text(UI) is the text in the object, in which said text is written under Text Input, and if you change that text the object updates, meanwhile below that we have the Main Setting, in which you can choose the font the size and the colour, to say a few, of the text.

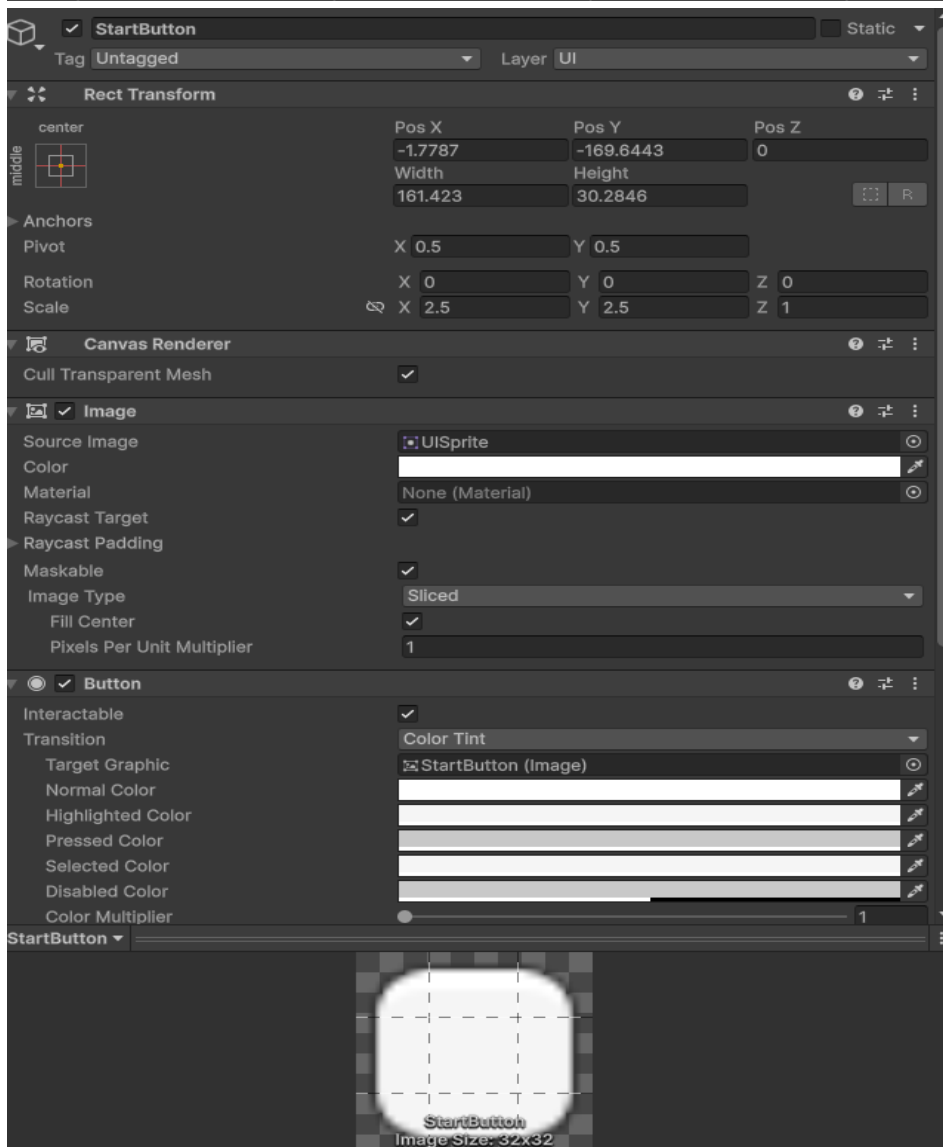

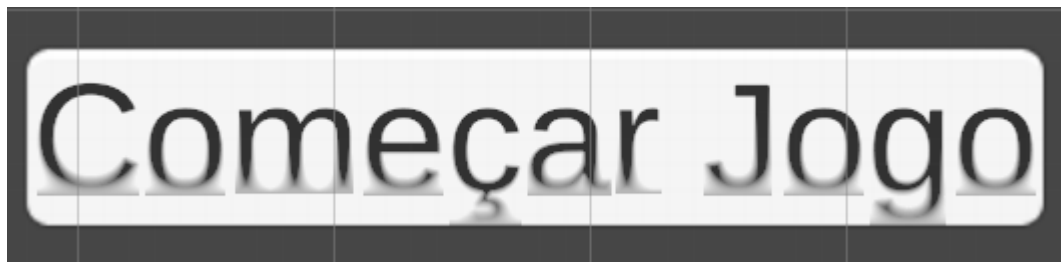

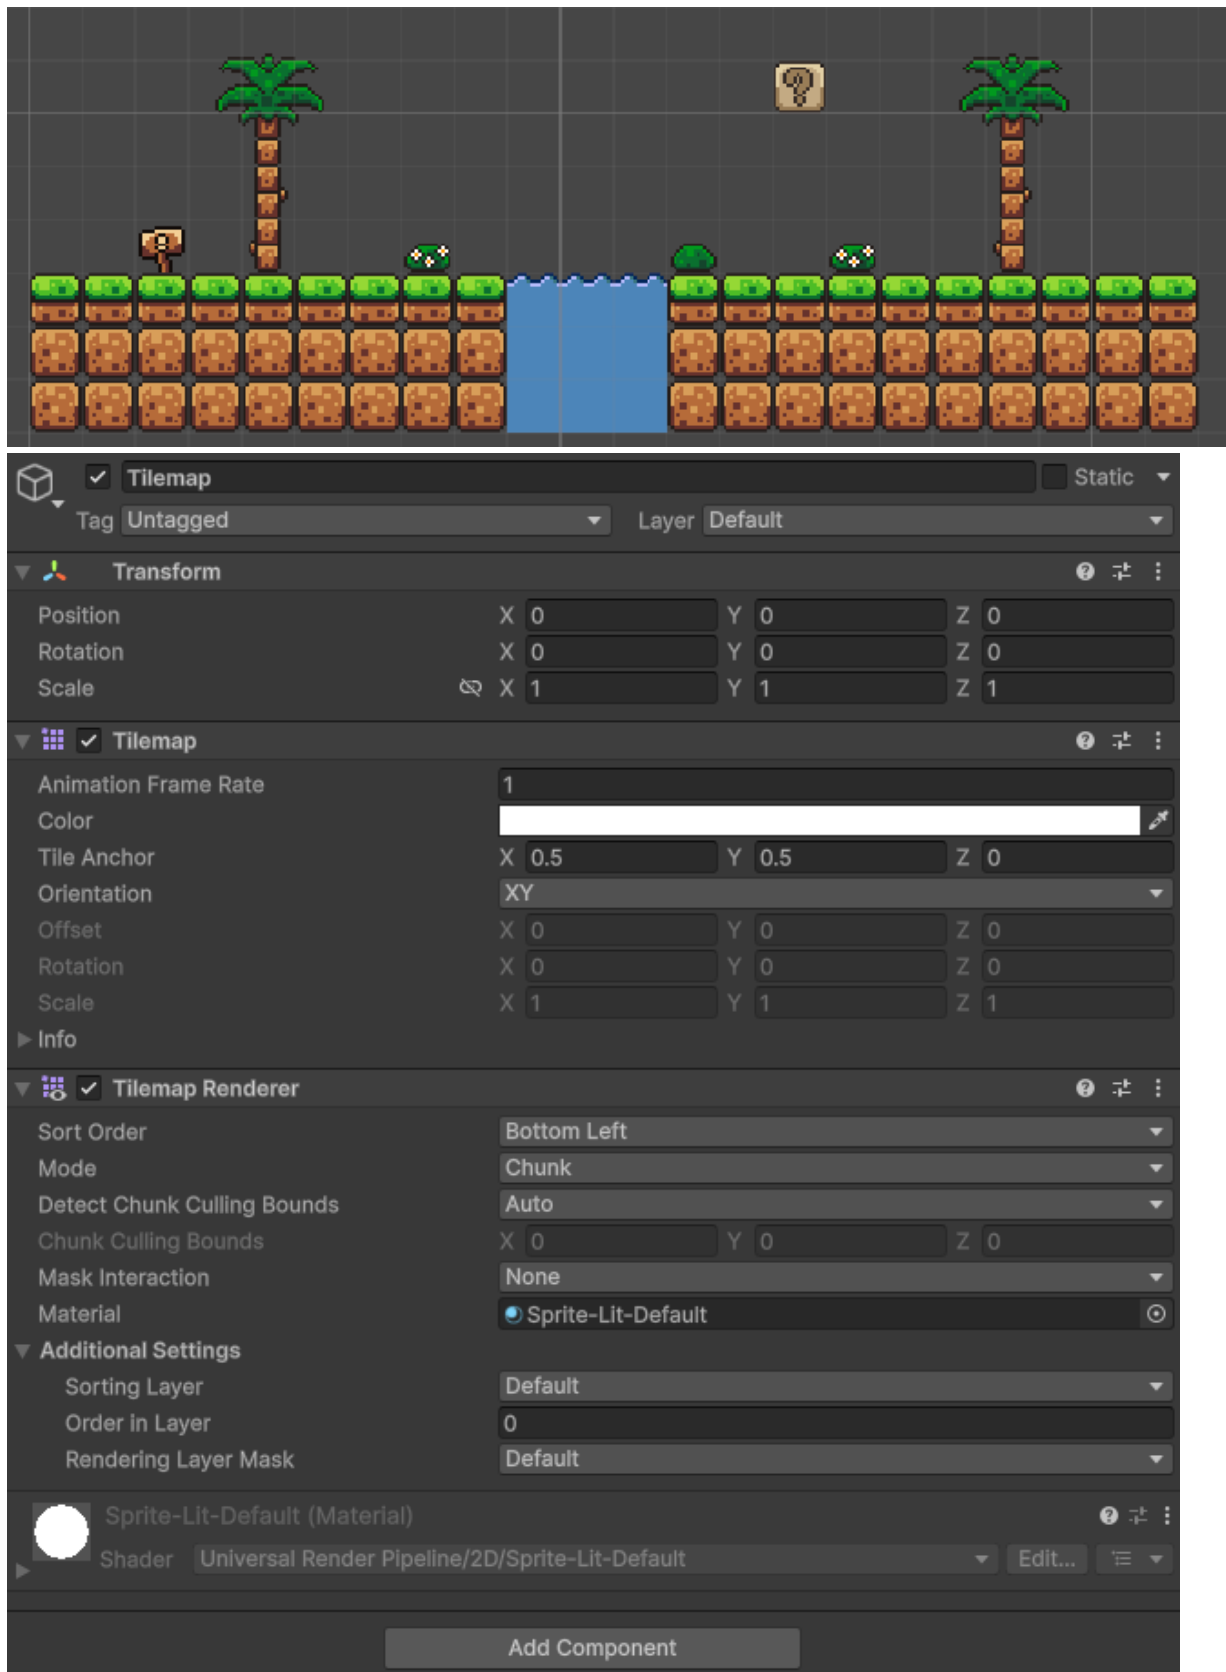

Image is the definitions of the image used for the object, which in this case is a button, it has options like “source image” which is what image is used for the button, from the programmer’s computer, and “Image Type” where you can determine if a image is used as is in the file, or sliced into 3 parts, the corners, walls and middle, which is used for text boxes and other objects that need to be scaled up without it messing up how the image looks

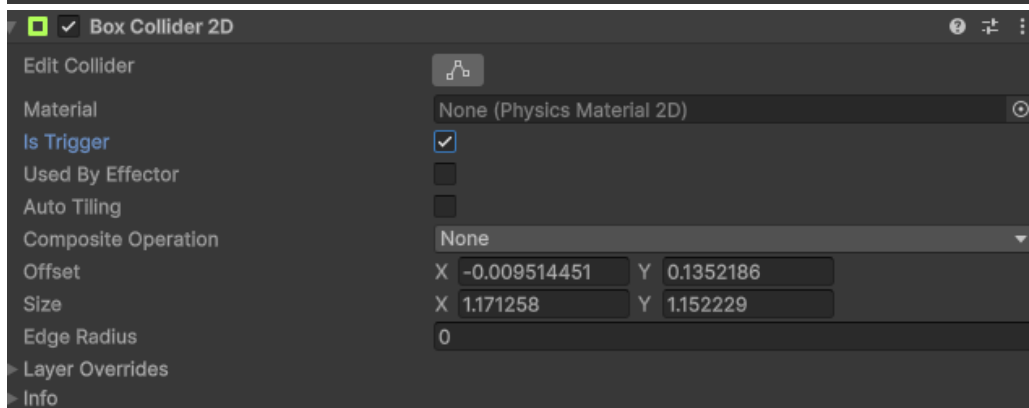

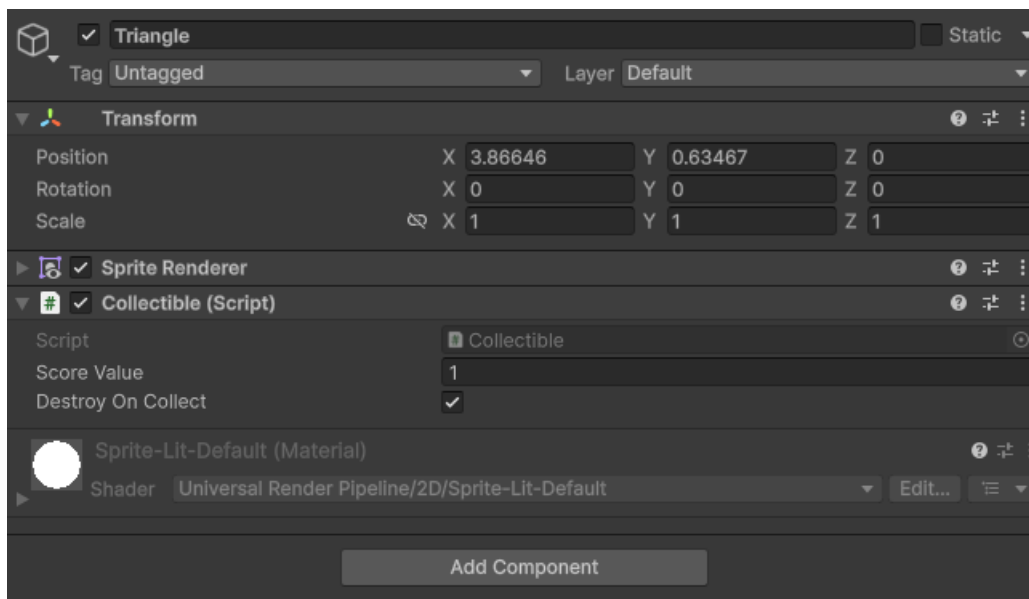

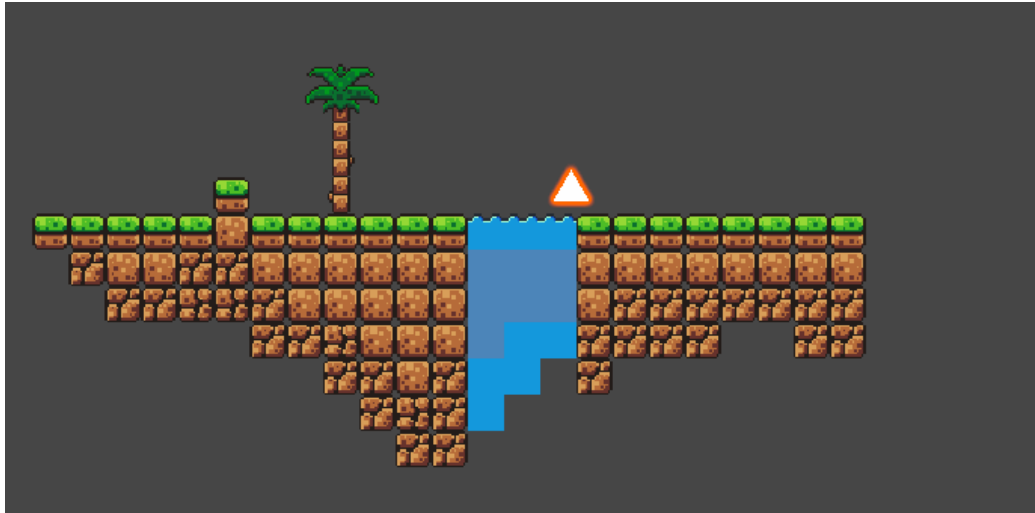

Button is the option that tells the object that it can be interactable in which you can choose to add a colour for the button to be when highlighted and pressed

Transform like rect transform in a previous entry, allow the editing of the position and sizing of the object, but this also allows the rotation of the object

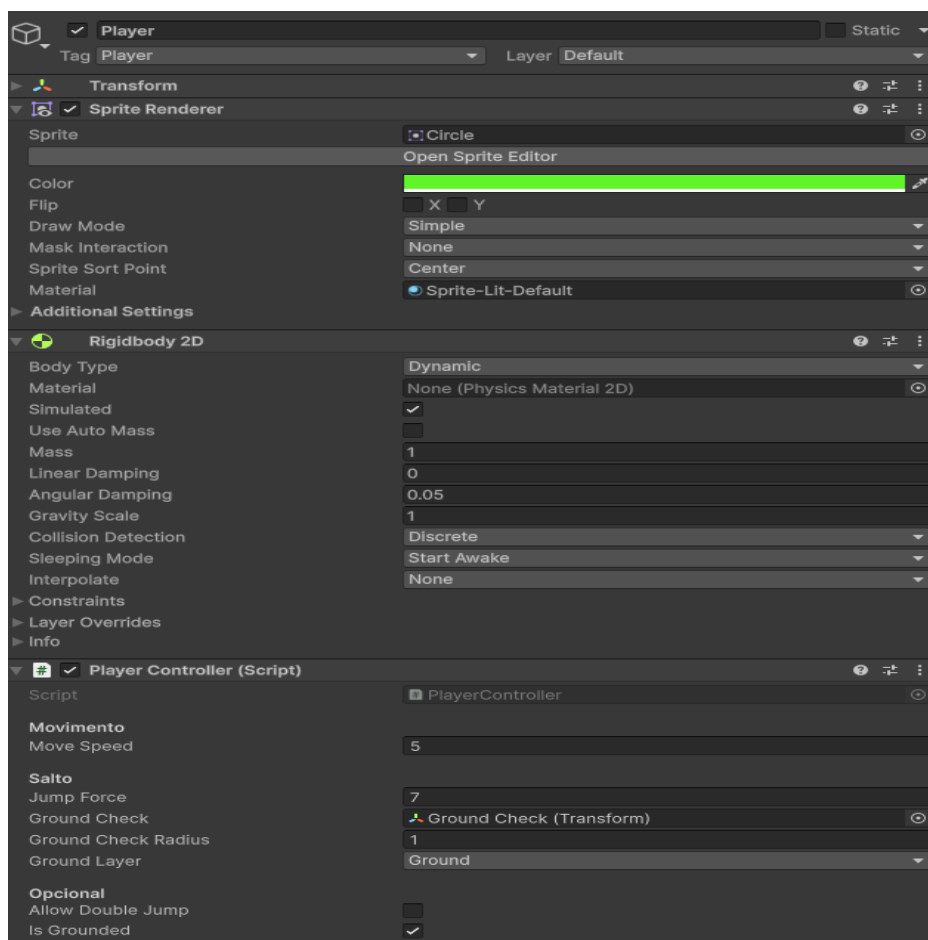

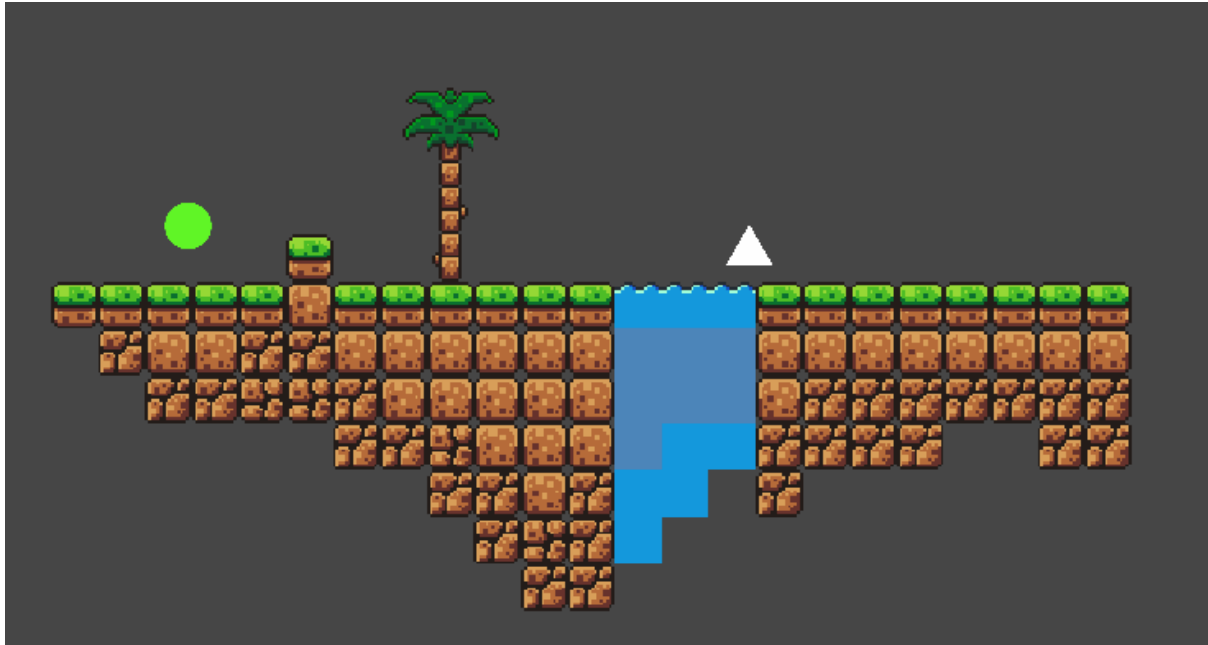

Tilemap is the component that allows the connection of the tiles into one map, in which you can use to animate or unite many tiles into either a big map (such as a object bigger than the basic scale of the tiles) or into a character

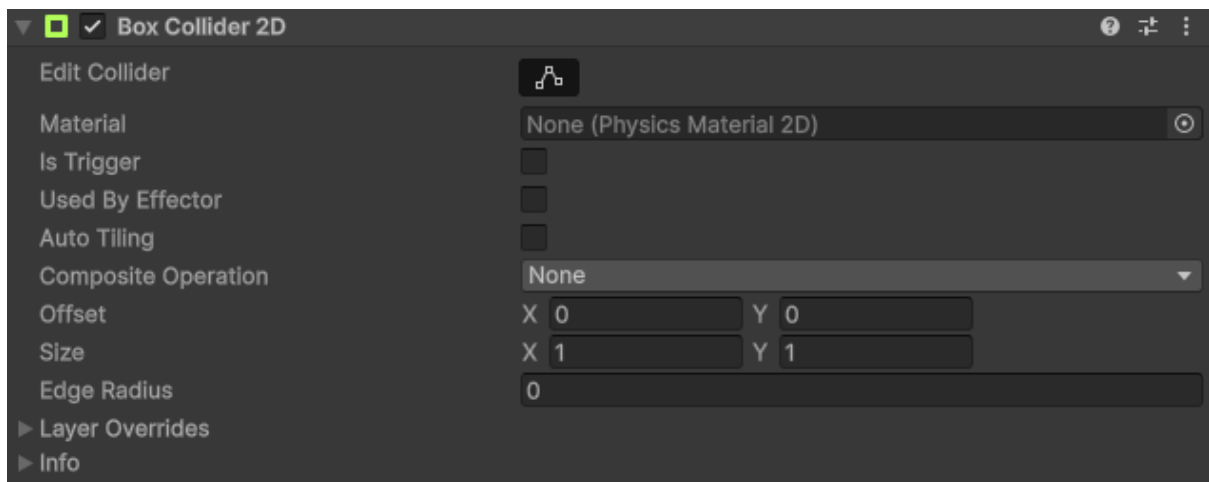

LEVEL 2

It can be assumed by the code that when the collectible object is touched by a “player”, it is destroyed and increases the score of the player by 1

LEVEL 3

The Player object has some components inside it, with the main thing being the rigid body, the player controller components and the box collider 2d, which allow the player to have mass, collision and gravity, which you can move around using the keys a and d to move around plus the space bar to jump and it can interact with the entire map of the level, including the collectible made before.

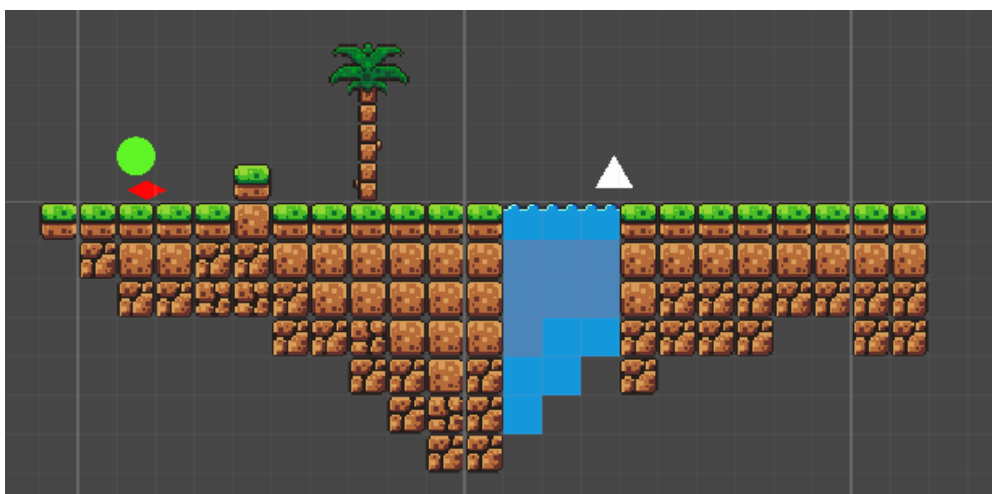

There are 3 different body types for rigidbody

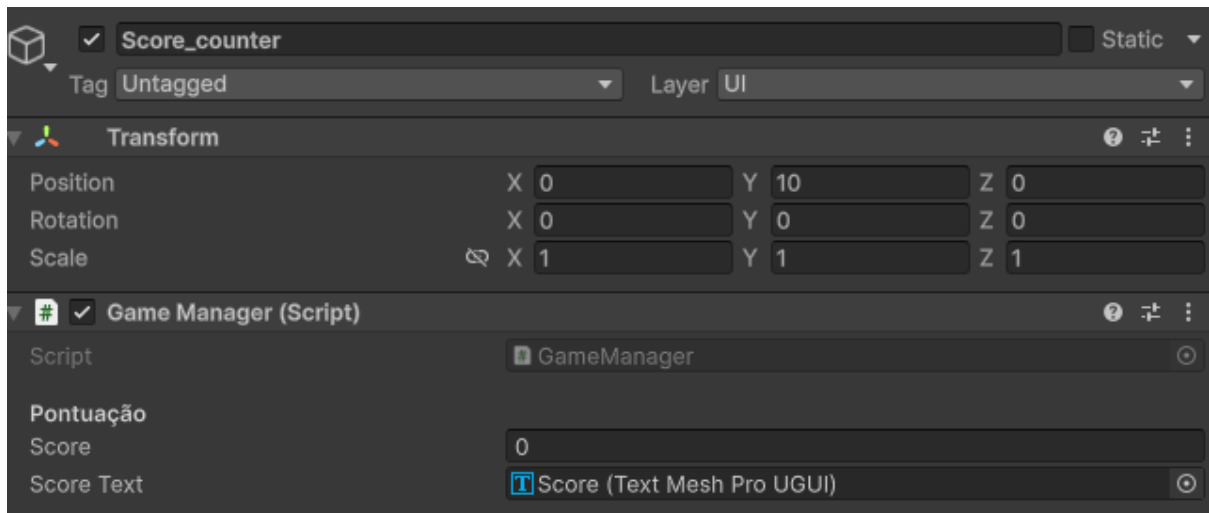

Dynamic, which moves around normally, when you press a key, it moves in that direction and when you let go it stops, it is affected by gravity and has collisions

Kinematic, which the movement is still “normal” if you press a key it moves in that direction, but you don’t have collisions with any object that isn’t a collectable and you don’t have gravity

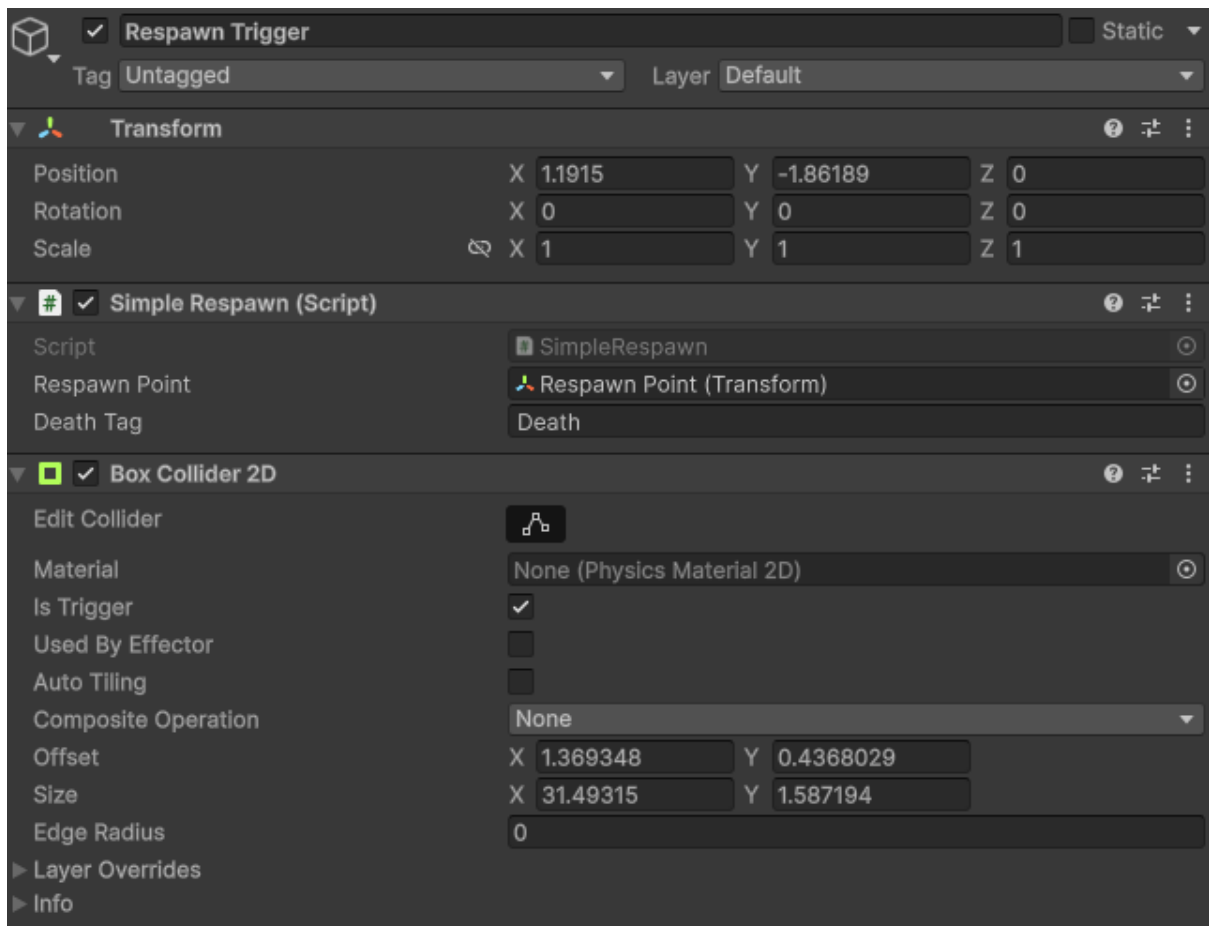

And finally Static, in which you can’t move, aren’t affected by gravity, and you can’t interact with anything, be it the map or a collectible if it was to “accidentally” be in the same spot as you.

LEVEL 4

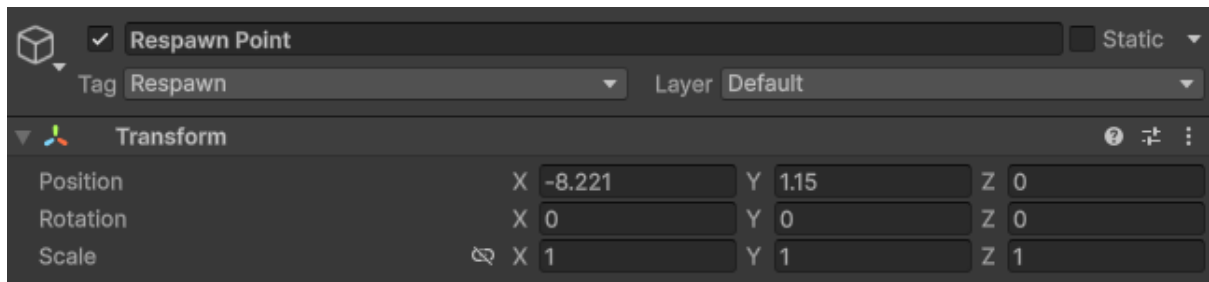

Score counter, keeps track of the score, and automatically updates the score text on the Text Mesh Pro object, when a collectible is obtained the score is increased by 1 in real time

The respawn trigger is a simple object that mainly just keeps the player inside an area by bringing them back to the respawn point, in this case, it's a long box below the area of the map that covers it from each corner of the map and then some

The respawn point is even simpler than the trigger, its just an object, this case shown with the image of a isometric diamond, which has the tag respawn, whenever the respawn trigger is activated, the player is brought to this area, without this the trigger would have no idea where to send, as such wouldn't do anything
